Supplementary Text

Supplementary Movie Legends

Supplementary Movie 1
The formation of a dsGUV out of the encapsulated GUVs.
Representative time-lapse fluorescence microscopy of the process showing the transformation of the encapsulated GUVs (ATTO 488-labeled DOPE) into a continuous supported lipid bilayer at the droplet inner interface. To transform the encapsulated GUVs into a supported lipid bilayer at the copolymer-stabilized droplet inner interface, 10 mM Mg$^{2+}$ was applied during droplet production or by means of pico-injection.

Supplementary Movie 2
Microfluidic release device.
The video shows the dsGUVs encounter the aqueous phase in a wide perpendicular channel. To minimize the mechanical impact on the dsGUVs at the oil/water junction, the droplets were decelerated using passive trapping structures within the microfluidic channels (i.e., rows of pillars separated by distances smaller than the representative droplets dimensions), which we designed for the efficient release of GUVs.

Supplementary Movie 3
Pyranine as a pH sensor inside microfluidic droplets.
The video shows water-in-oil droplets immobilized in a microfluidic trapping device. The pH-sensitive fluorophore pyranine (concentration: 50µM) in ATP activity buffer was encapsulated into the droplets. To change the pH inside the droplets via the oil phase, acidic oil (containing 1µL of trifluoroacetic acid per 1 ml FC40 oil) and basic oil (containing 1µL of propyl amine per 1 ml FC40 oil) were alternately flushed through the device. As a result, the pH inside the droplets changed accordingly from acidic to basic and vice versa. The encapsulated fluorophore pyranine was simultaneously excited at 405 nm and 458 nm wavelength and the corresponding emission signal was recorded. Dominant 405 nm detection signal indicated by blue color corresponds to basic pH, dominant 458 nm detection signal indicated by green color corresponds to acidic pH.

Supplementary Methods

Preparation of large unilamellar vesicles (LUVs) and free-standing giant unilamellar vesicles (GUVs).
Lipids used in this study: 1,2-dioleoyl-sn-glycero-3-phosphocholine (DOPC), 1,2-dioleoyl-sn-glycero-3-phosphoethanolamine (DOPE), 1,2-dioleoyl-sn-glycero-3-phospho-L-serine (DOPS), 1,2-dioleoyl-sn-glycero-3-[(N-(5-amino-1-carboxypentyl)iminodiacetic acid) succinyl] (DGS-NTA), 1,2-dioleoyl-sn-glycero-3-phosphoethanolamine-N-(lissamine rhodamine B sulfonyl) (RhB DOPE), 1-palmitoyl-2-hydroxy-sn-glycero-3-phosphate (Phosphatidic acid), L-α-phosphatidylcholine (Egg PC), L-α-phosphatidylglycerol (Egg PG) were purchased from Avanti (Avanti Polar Lipids, USA) and used without further purification. ATTO 488 1,2-dioleoyl-sn-glycero-3-phosphoethanolamine was purchased from ATTO TEC (Siegen, Germany);
To obtain the formation of dsGUVs, solutions of LUVs or GUVs, consisting of different lipid compositions, were generated according to previously reported protocols.¹ ² In brief, lipids were dissolved in pure chloroform, mixed at desired composition and concentration and dried...
under a gentle stream of nitrogen. To remove traces of the solvent, lipids were kept under vacuum in a desiccator for roughly 1 h. Dried lipids were then resuspended by addition of the desired buffer, followed by one hour of vortexing. LUV size was homogenized by extruding the solution 7 times through a polycarbonate filter (Whatman, Germany) with a pore size of 50 nm using an extruder (Avanti Polar Lipids, USA). The mean LUV diameter distribution was determined to be 100 ±10 nm using DLS. Solutions containing LUVs were stored at 4°C for not longer than 48 h or used immediately after production.

GUVs consisting of DOPC:DOPE:DOPS 8:1:1, including 1% ATTO 488-labeled DOPE were formed using the electroformation protocols as described previously. In brief, lipid mixtures at the desired concentration (from 1 to 5 mM) were dissolved in pure chloroform and spread onto two indium tin oxide (ITO) coated glasses (Sigma-Aldrich, Germany). Subsequently, the chamber was filled with Milli-Q water (Millipore filtered) and sealed with two-component glue (Twinsil Picodent GmbH, Germany). An alternating electrical potential of 10 Hz at 1 V amplitude was applied for 2 h to form GUVs. Finally the GUVs were collected using a syringe. Following vesicles production, the solutions were used immediately for encapsulation into microfluidic water-in-oil copolymer-stabilized droplets.

**Block copolymer surfactant synthesis.** Three types of block-copolymer surfactants were synthesized according to protocols reported earlier and used to produce droplets: Two triblock-copolymers PFPE(7000 g/mol)-PEG(1400 g/mol)-PFPE(7000 g/mol) (TRI7000) and PFPE(2500 g/mol)-PEG(600 g/mol)-PFPE(2500 g/mol) (TRI2500) and a gold-linked diblock-copolymer surfactant Au-PEG(436 g/mol)-PFPE(7000 g/mol). Following synthesis, triblock surfactants were mixed separately with gold-linked surfactants and dissolved in FC-40 fluorinated oil (3M, USA) to the final concentrations of 2.5 mM and 3 μM for triblock and gold-linked surfactants, respectively. NOTE: The two types of triblock copolymer surfactants (i.e. TRI7000 and TRI2500) mixed with gold-linked surfactants were tested and compared in all experiments. If not stated otherwise, the same results were observed.

**Droplet-based microfluidics.** Droplet-based microfluidic devices made of PDMS (Sylgard 184, Dow Corning, USA) were prepared by photo- and soft-lithography methods as described previously. To control the droplet diameter during their creation, two different nozzle designs at the flow-focusing junction were implemented (Supplementary Figures 4 A and B). Syringe pumps PUMP 11 ELITE (Harvard apparatus, USA) were used to control flow rates of 120 μL/h for the aqueous phase and 160 μL/h for the oil phase as required for stable droplet creation (diameter d = 40 μm) at the rate of 1 kHz. In case of big droplets (d = 100 μm) the flow rates were adjusted to 650 and 850 μL/h for aqueous and oil phases, respectively to achieve a stable droplet creation at a rate of 1 kHz.

Due to the variety of required cellular components in the droplets the microfluidic device was integrated with small and compact electrodes to apply an electric potential. Electrical fields allow destabilization (poration) of surfactants and lipid bilayers towards controlled injection (pico-injection) of different cellular components into the droplets. The design of the droplet-based pico-injection unit was adapted from Abate et al. Droplets were introduced into the device using a MFCS-EZ flow control system (Flui gent, France). The spacing between the droplets was controlled through addition of oil via the second oil channel (Supplementary Figure 4F). Following separation step, isolated droplets passed an alternating electrical field (frequency 1kHz, potential 250 V) generated by HM 8150 signal generator (HAMEG, Germany) and amplified by 623B-H-CE amplifier (TREK, USA) and two electrodes made of...
Indalloy 19 (51% indium, 32.5% bismuth, 16.5% tin, GPS Technologies, Germany). This process destabilizes the droplet copolymer shell and lipid bilayer and allows introduction of bio-reagents via a pressurized injection channel (Supplementary Figure 4G). The injection volume can be ranged between 1 to 100 pl, dependent on the applied pressure.

For analysis, droplets were collected and transferred to the observation chamber (Supplementary Figure 5). The chamber was made of two single or sandwiched stripes of double face sticky tapes (Tesa, Germany. Thickness ≈ 80 µm or 160 µm for analysis of small and large droplets, respectively) as spacers, glued between two cover slips (Carl Roth, Germany). Finally, the chamber was filled with surfactant-containing oil and closed by two-component glue (Twinsil, Picodent GmbH, Germany).

**Glass coatings for integrin-reconstituted GUVs adhesion experiments.** To validate the biological functionality of the reconstituted integrin after the process of release, the adhesion of the integrin-reconstituted GUVs to fibrinogen-, fibronectin-, collagen-, and BSA-coated glass surfaces was examined and compared (Supplementary Figure 8). Therefore, dsGUVs with reconstituted αIIβ3 integrin were formed and released as described in (Online Methods). For adhesion experiments integrin activation buffer (20 mM TRIS/HCl, pH 7.4, 50 mM NaCl, 0.5 mM CaCl2, 1 mM MnCl2 and 1 mM MgCl2) was used inside and outside the GUVs. Following release the integrin-reconstituted GUVs were transferred to an observation chamber (Supplementary Figure 5) containing fibrinogen-, fibronectin-, collagen-, or BSA-coated glass slides. The adhesion was analyzed after 8 h incubation at 4°C to allow the integrin to interact with the different coatings. For these experiments fibronectin isolated from human plasma was dissolved in PBS, collagen Type I (calf skin, Sigma-Aldrich, Germany) was dissolved in 0.1 M acetic acid and fibrinogen (human plasma, Merck Millipore, Germany) was first dissolved in 8.5% NaCl and for the incubation transferred to PBS.

For coating the glass surface of the observation chamber, pretreated glass slides (O2 plasma, 200 W, 30 s) were incubated with 0.1 mg/ml protein solution (8.5 µg/cm²) over night at 4°C (fibrinogen and collagen) or 1.5 h at room temperature (fibronectin). For the BSA coating the glasses were incubated with 10 mg/ml BSA in PBS for 2 h at room temperature, followed by a washing step with PBS and water for each 5 min. After incubation, the glass slides were air dried over night at 4°C. The coverslips for the observation chamber were passivated with BSA.

**Microscopy.** All experiments were performed on a Leica SP5 confocal microscope (Leica Microsystems, Germany) equipped with an argon and a white light laser. The measurements were conducted at 25°C and in case of microtubule analysis at 37°C. Droplets, sealed in an analysis chamber, were observed via a 63x oil objective (HCX PL APO 63x/1.40-0.60; Leica Microsystems GmbH, Germany). Fluorophores were exited at 488, 550 and 555 nm and the detection windows were set at 498-540 and 560-620 nm and 565-625 nm in case of ATTO 488, Rhodamine B and TAMRA-labeling, respectively. The pinhole for data acquisition was set to 1 Airy unit, which corresponds to an Airy disk diameter of 96 µm and 0.9 µm thickness of the optical slice.

**FRAP measurements.** Due to the density differences between the aqueous droplets and the surrounding oil (1.0×10³ vs. 1.9×10³ kgm⁻³), the droplets ascend towards the upper slide of the observation chamber (Supplementary Figure 5). In this position, the droplets were scanned in z-direction until the bottom slice of the droplet was identified. The base of the droplet was chosen as a focal plane for FRAP measurements in order to exclude any influence from the cover slip at the chamber ceiling. A circular spot with a diameter of 5 µm was selected as the bleaching area. It should be noted that in case of FRAP measurements performed inside the droplets or on their periphery the actual bleaching area was measured and corrected for each measurement due to distortion of the optical path as a reason of diffraction/refraction at the
oil/water interface. Time course of each FRAP experiment included 10 pre-bleaching images, 2 to 10 bleach cycles to eliminate the fluorescent signal and 50 to 200 post-bleaching images to record the fluorescence recovery. The bleaching time was adjusted to each fluorophore and laser used in the experiments, the acquisition frequency of post-bleaching images was adapted to the total recovery time. The average diffusion coefficient for each experiment and its standard error were calculated from at least 20 measurements. The analysis followed the protocols proposed by Axelrod et al.9 and Soumpasis10 as described in Supplementary Note 3.

**Raman spectroscopy.** For Raman spectra collection released GUVs or dsGUVs were injected into the observation chamber (Supplementary Figure 5). GUVs or dsGUVs, sealed in an analysis chamber, were observed via a 100x oil objective (NA 1.2, Zeiss, Germany) using a confocal Raman microscope (Alpha300RA, WITec GmbH, Germany). To collect Raman scattered light, the same objective was used for focusing a 532 nm laser (20 mW, spot size 350 nm) onto single GUVs or dsGUVs. The acquisition time was fixed to 2.14 seconds with five accumulations for each collection window. At the end of spectra collection the location of the observed subject was investigated and, in case the location was preserved the collected data was saved. The representative Raman spectra of the dsGUVs and of the released GUVs can be observed in Supplementary Figure 7.

**Fluctuation analysis.** Fluctuation analysis was performed following the protocol described earlier.11 The GUVs were placed in a chamber made of two cover slips and a 2 mm-thick ring made of Teflon, and observed under phase contrast. The data was acquired at room temperature ~23°C. The acquisition of five thousands of snapshots was done by high-resolution camera (pc.o.edge, PCO AG, Kelheim, Germany). More than 10 vesicles per type of sample were examined.

The bending rigidity of vesicles released from droplets was measured and compared to that of vesicles prepared following the method of electroformation12, 13 or gel-assisted swelling.14 The membrane composition was DOPC:POPC:Chol (4:4:2) in mole ratios and small amount of the ATTO 488 labeled DOPE was also added at concentration of 1 mol% of total lipid. The buffer composition used for fluctuation analysis of the released GUVs was adjusted to be similar to integrin activation buffer within the GUVs (20 mM TRIS/HCl, pH 7.4, 50 mM NaCl, 0.5 mM CaCl₂, 1 mM MnCl₂ and 1 mM MgCl₂). The bending rigidity of the released vesicles was measured to be 21.5 ± 3.4 k_BT (standard deviation). This value lies in the range of typical values reported for the bending rigidity of PC membranes,15 suggesting that the bilayers are clean of impurities. The methods of electroformation and gel-assisted swelling did not yield suitable vesicles (the vesicles were small and with defects or multilamellar) when grown in the buffer used for the preparation of dsGUVs. Therefore, we electroformed vesicles with the same membrane composition but in solution of 1 mM MgCl₂. The bending rigidity values for these membranes were found to be 25.3 ± 3.0 k_BT ideally corresponding to the data for released vesicles.

**Supplementary Notes**

**Supplementary Note1. Calculation of minimal lipid concentration required to form a continuous lipid bilayer inside droplets - dsGUV:**

The following lipid concentration calculation is done for droplets with 75 µm radius. The volume $V_{droplet}$ and the surface area $A_{droplet}$ of a spherical droplet is given by
\[ V_{\text{droplet}} = \frac{4}{3} \pi r^3 = 1.8 \times 10^6 \mu m^3 = 1.8 nL \]

and

\[ A_{\text{droplet}} = 4\pi r^2 = 7.1 \times 10^{10} nm^2. \]

Assumption: Average area occupied by a single phospholipid in a lipid membrane equals\(^{16}\)

\[ A_{\text{headgroup}} = 0.7 \, nm^2. \]

The amount of lipids per droplet needed to form a complete lipid bilayer is therefore:

\[ N_{\text{lipids}} = 2 \times \frac{A_{\text{droplet}}}{A_{\text{headgroup}}} = 2.3 \times 10^{11}. \]

Thus, the lipid concentration required to form a lipid bilayer inside droplets is

\[ c = \frac{N_{\text{lipids}}}{V_{\text{droplet}} \times N_A} = \frac{6}{r \times N_A \times A_{\text{headgroup}}} = 190 \mu M. \]

The concentration for droplets with different radii used in this study is \(c(r=50 \, \mu m) = 285 \, \mu M\) and \(c(r=20 \, \mu m) = 712 \, \mu M\).

For the experiments an excess of \(\approx 15\%\) in lipid concentration was used for the following two reasons: 1) to compensate for possible lipids loss during the production; and 2) to compensate for volume increase due to pico-injection.

To validate experimentally the relevance of theoretically estimated lipid concentration, we systematically varied the amount of fluorescently-labeled lipids injected into monodisperse droplets and recorded their fluorescence intensity at the droplet interface. In case of minor lipid amount which would not cover the complete inner surface of the droplet we did not see the assembly of smaller GUVs than the size of the droplet itself. Instead we observed fusion of available lipids at the inner wall of the droplet. A plot of the measured data is shown in Supplementary Figure 1. Considering the diameter of 120μm of the droplets used in this experiment, a calculated concentration of 237 μM lipids is required for full bilayer coverage. As can be observed in Supplementary Figure 1, the intensity values are increasing approximately linear up to the theoretical estimated concentration. At elevated concentration the intensity reaches a plateau. It should be noted that at higher concentrations the excess lipids form aggregates of liposomes at the droplet interface. Inhomogeneous aggregation of liposomes on the droplet’s periphery affecting precise estimation of the intensity. Therefore, higher deviation in the recorded intensity at 500μM is attributed to this effect.

Supplementary Note 2. Calculation of vesicle diffusion in microfluidic droplets

Assuming 3D Brownian motion, the mean square displacement \(\langle r^2(t) \rangle\) of a particle in solution is

\[ \langle r^2(t) \rangle = 6D(t). \]

The mean time \(\langle t \rangle\) needed for the particle to travel the distance \(\sqrt{\langle r^2(t) \rangle}\) is therefore
\[ \langle t \rangle = \frac{\langle r^2(t) \rangle}{6D}. \]

The diffusion coefficient \( D \) of a spherical particle with radius \( R \) in a solution with viscosity \( \eta \) for a given temperature \( T \) is

\[ D = \frac{k_B T}{6\pi \eta R}. \]

Therefore, the average time for a vesicle with radius \( R \) needed to diffuse from the center of the droplet to the periphery \( \left( \sqrt{\langle r^2(t) \rangle} = 20 \, \mu m \right) \) is

\[ \langle t \rangle = \frac{\langle r^2(t) \rangle 6\pi \eta R}{k_B T}. \]

Assuming an aqueous solution with \( \eta = 0.1 \, Pa \cdot s \) and a temperature \( T = 25^\circ C \), the average time for all vesicle to diffuse from the centrum to the periphery of the droplet with diameter 40 \( \mu m \) is

\[ \langle t(R = 50 \, nm) \rangle \approx 15 \, s \]

and

\[ \langle t(R = 5 \, \mu m) \rangle \approx 25 \, min. \]

### Supplementary Note 3. Evaluation of FRAP data

The analysis followed a protocol proposed by Axelrod et al.\textsuperscript{9} and Soumpasis.\textsuperscript{10} To correct the background noise \( I_{bg} \), the detector signal was measured in the oil phase using the same settings as for the FRAP measurements. \( I_{bg} \) was subsequently subtracted from all the measured intensity values. Average intensity values of the bleaching spot, \( I(t) \), and as a reference of the whole droplet base, \( T(t) \), were extracted from the recorded images. \( I(t) \) and \( T(t) \) were normalized by the averages of the prebleaching values, \( I_{pb} \) and \( T_{pb} \). To correct for photofading the intensities of the bleached spot were multiplied with the reciprocal, normalized intensities of the droplet base, \( T(t) \). Thus the normalized and corrected intensities, \( I_{nor} \), were calculated as

\[ I_{nor} = \frac{I(t) - I_{bg}}{I_{pb} - I_{bg}} \frac{T_{pb} - I_{bg}}{T(t) - I_{bg}}. \]

A nonlinear least-square fit was then applied using MATLAB R2015a SP1 (Mathworks, USA) to fit an exponential function \( f(t) \),

\[ f(t) = a \left( 1 - \exp(\lambda \cdot t) \right), \]

to the normalized intensities, \( I_{nor} \). The resulting values of the coefficient \( \lambda \) were then used to calculate the half-recovery time \( \tau_{1/2} \) for each bleaching experiment,

\[ \tau_{1/2} = \frac{-\log(0.5)}{\lambda}. \]
The diffusion coefficient, $D$, is related to the half-recovery time $\tau_{1/2}$ via the square radius of the bleaching spot, assuming Gaussian bleaching profile,

$$D = 0.32 \frac{r^2}{\tau_{1/2}}.$$

The average diffusion coefficient for each experiment and its standard error were calculated from at least 20 measurements (Supplementary Figure 9).

**Supplementary Note 4. Calculation of number of integrin proteins that might be reconstituted in dsGUVs.**

Droplet surface area:

$$S(r = 20\mu m) = 5026 \mu m^2$$
$$S(r = 50\mu m) = 31416 \mu m^2$$

Area of a lipid in a membrane (from literature)

$$A_{lip} \approx 0.7nm^2$$

Cross-section of the transmembrane domain of integrin (two $\alpha$ helices).\(^{17}\)

$$A_{int} = 2nm^2$$

Supplementary Figures

Supplementary Figure 1
Fluorescence intensity of the lipids at the droplets interface as a function of encapsulated lipid concentration.

To validate experimentally the relevance of theoretically estimated lipid concentration (237 μM, Supplementary Note 1), we systematically varied the amount of fluorescently-labeled lipids (egg PC:egg PG, 9:1, including 0.5 % ATTO 488-labelled DOPE) encapsulated into 120 μm diameter monodisperse droplets and recorded their fluorescence intensity at the droplet interface. In case of lipid concentration lower than 237 μM no smaller GUVs than the size of the droplet itself were observed. Instead fusion of available lipids at the inner wall of the droplet was detected. As can be observed, the lipid fluorescence intensity values are increasing approximately linear up to the theoretical estimated concentration. At higher lipid concentration the intensity reaches a plateau. It should be noted that at higher concentrations the excess lipids form aggregates of liposomes at the droplet interface. Inhomogeneous aggregation of liposomes on the droplet’s periphery affecting precise estimation of the intensity. Therefore, higher deviation in the recorded intensity at 400μM lipid concentration is attributed to this effect. The mean integrated intensity values and their standard deviation, indicated by the error bars, were derived from intensity profiles taken from twenty individual droplets, each intersecting the membrane twice rectangularly.
Supplementary Figure 2
Partial vesicle fusion due to 10 mM Ca^{2+} ions addition.

Representative fluorescence image of lipid distribution (DOPC:DOPE:DOPS 8:1:1, including 1% ATTO 488-labeled DOPE) within microfluidic water-in-oil droplets, containing 10 mM Ca^{2+} ions (CaCl_2), measured 1 h after creation.

Supplementary Figure 3
Biofunctionalization of dsGUVs via DGS-NTA(Ni)lipids.

In order to test the functionalization of dsGUVs, (His6)-GFP was pico-injected into droplets. (A) For droplets containing DOPC:DGS-NTA(Ni), 9:1 (220 μM), (His6)-GFP was linked to the dsGUVs at the droplets periphery. (B) An equally distributed fluorescence signal was observed when no anchoring points were present (here: dsGUVs consisting of DOPC lipids only). (C) Representative FRAP experiments on the mobility of (His6)-GFP immobilized to the
copolymer-stabilized droplet interface (upper trace) or the dsGUV (lower trace). The bleached area is encircled in the pre-bleach frame and the recovery time (seconds after bleaching) is indicated on top of the fluorescence recovery frames. Scale bar 10 µm.

Supplementary Figure 4
Droplet-based microfluidic functional units.

Presentation of different droplet-based microfluidic operating units used in this research. (A) and (B) show representative images of the flow-focusing junctions for droplets production with a diameter of 40 and 100 µm, respectively. (D) shows a microfluidic droplet production device with two aqueous inlet channels (blue) and one oil channel (red). This device was implemented in actin-related experiments in order to avoid actin polymerization prior to droplet formation. Inset (C) and (E) show representative fluorescence images of the two phases for actin polymerization within the droplets. Bright phases represent the actin solution containing Alexa 488-labeled G-actin. The second phase contains all necessary bio-molecules for polymerization and bundling of actin. The solutions have a contact time in the millisecond range before getting encapsulated. Images (F) and (G) represent the pico-injection device for controlled introduction of different cellular components into droplets. (F) The spacing between the droplets carrying different biologically-active molecules is controlled through addition of oil via the second oil channel. (G) An alternating electric potential (1 kHz and 250 V) reduces the stability (poration) of the surfactants-lipid layer at the droplet interface for an aqueous injection of reagents from a pico-injection channel (injection volume can be ranged between 2 to 100 pl, dependent on the applied pressure). The injection process can be visualized by injection of ATTO 488-labeled FoF1-ATP synthase (H), using fluorescence microscopy.
Supplementary Figure 5
Observation chamber and analysis setup.

(A) Shows the design of an observation chamber for droplet analysis. (B) Magnified cross-section representation of the analysis chamber. Due to the density differences, droplets rise to the top of the chamber. Confocal microscopy was used to scan the droplet in order to find the bottom plane. The lowest slice of the droplet was chosen as a focal plane for FRAP measurements in order to exclude any influence of stiff objects like in the case of the coverslip and the upper parts of the droplet. (C) Example of a FRAP experiment performed on dsGUV containing GFP-linked DGS lipids. The image shows a circular bleached spot with a 5 µm diameter.

Supplementary Figure 6
Release of dsGUVs, preservation of content and checking for oil residues.

To evaluate if the lipid bilayer stayed intact during the release process the (A) oil phase (ATTO 520, yellow), the (B) lipid bilayer (RhB DOPE, green), the (C) encapsulated (HyLite 405, blue) and (D) continuous water phase (Alexa 647, red) were labeled with distinctive fluorophores. (E) A composite image of all channels. On the bottom left of each frame is the continuous oil phase containing multiple dsGUV encapsulating aqueous medium. The remainder of the frame is filled with a continuous aqueous phase containing a single released GUV. (A-D) The insets display a line profile intersecting the released GUV along the indicated white line for the respective fluorophore. (A) In the oil channel, no traces of remaining oil can be detected on the released GUV. (B) The fluorescent signal of the RhB DOPE is stronger compared to the dsGUV.
This is likely due to reduced diffraction and refraction. (C) and (D) show that no mixing between the aqueous phases was detected.

**Supplementary Figure 7**

Raman spectra of dsGUVs and the released GUVs.

Raman microscope was used to perform Raman spectroscopy on released GUVs to provide a method for the detection of oil/surfactant residues in the released GUVs. (A) Comparison of Raman spectra collected from the solution of surfactants in FC40 oil (brown) and from the SUVs (green), consisting of 4:4:2 of DOPC, POPC and cholesterol, respectively. Carbon-hydrogen stretching vibration of lipid tails indicated by arrow between 2800 and 3000 cm\(^{-1}\). The obtained FC40 oil spectrum in this study present similar peaks as published before. (B) Representative Raman spectra collected through the water oil interphase of the single dsGUV as indicated by the red line in the insert bright-field image. In sake of clarity of presentation the spectra collected from the oil and water phases were brown and blue colored, respectively. (C) Representative Raman spectra collected through the water-lipid interphase of the released GUV as indicated by the red line in the insert bright-field image. In sake of clarity of presentation the spectra collected from the water phases and the lipid bilayer were blue and green colored, respectively. Importantly, no characteristic peaks of the FC40 oil/surfactant were detected.
within the collected spectra. Raman intensity of the carbon-hydrogen stretching vibration of lipid tails (indicated by arrow) was plotted over the screening distance.

Supplementary Figure 8
Release of integrin-reconstituted GUVs and their functionality assessment.

Representative 3D reconstitution of confocal images of recovered integrin-reconstituted GUVs and their interactions with (A) fibrinogen- (C) fibronectin- (D) collagen- and (E) BSA-coated glass surfaces. The integrin-reconstituted GUVs show strong or moderate adhesion to fibrinogen- or fibronectin-coated glass surfaces, respectively. In comparison, only very weak to no interaction was detected for collagen or BSA-coated surfaces. The merged fluorescence signals consist of ATTO 488-labeled DOPE lipids and TAMRA-labeled αIIbβ3 integrin. (B) Shows the control experiment in which due to the absence of reconstituted integrin no interaction between the GUV and the fibrinogen-coated glass surface was observed.

Supplementary Figure 9
Representative recovery curves. (A) Shows representative raw data acquired for a FRAP measurement on a dsGUV. The data consists of the average intensity values of the bleaching spot and of the whole droplet area in focus. A horizontal dotted line was added as a guide for the eye to indicate photo-fading. Before analysis, all data points were corrected for background. Furthermore, data points were normalized by the average pre-bleaching value and the inverse of the average intensity of the whole droplet in focus was multiplied to the values of the bleaching spot, to correct for photo-fading. The resulting normalized intensity values of the fitting points and fitting curve are presented for the same dsGUV (B). Representative normalized fluorescence recovery curves obtained from the measurements performed on released and produced by electroformation GUVs are presented (C) and (D), respectively. In the FRAP measurements as presented in A-D the same lipid composition containing 0.5 % ATTO 488-labeled DOPE was used as fluorescent marker. (E) and (F) show represented normalized fluorescence recovery curves obtained from the measurements performed on reconstituted TAMRA-labeled integrin proteins in dsGUVs with and without interaction with RGD peptides on the surfactant layer, respectively.

Supplementary Figure 10
Pyranine as a pH sensor within the dsGUVs.

Pyranine was used as a sensor to monitor changes of the dsGUV internal pH. To calibrate the system, dsGUVs were produced with a given pH ranging from 5 to 10 with 1µM pyranine in the aqueous solution. These dsGUVs were then excited at 405 nm and 458 nm wavelength. The figure shows the variation of the fluorescence intensity ratios as a function of a given pH.
